

# Large-scale secondary circulations in the COSMO-CLM

**Nico Becker**  
Institut für Meteorologie  
Freie Universität Berlin

**COSMO / CLM / ART User Seminar 2016**  
**Offenbach, 09.03.2016**

## What is the aim of an RCM?

- “[...] having **fine-scale features** at scales that are absent in the initial and lateral boundary conditions.” (*Antic 2004*)

## However...

- RCM simulations also show **large-scale deviations** from the driving data!
- Controversial discussion whether this is desired in RCMs (*e.g. von Storch et al. 2000*)
  - RCMs are able to improve the large scales (*Diaconescu et al. 2013*)
  - But large-scale deviations can cause **problems at the lateral boundaries**

Which mechanisms are responsible for large-scale deviations of RCMs from their driving data?

# Outline

## 1) Splitting of the RCM wind fields

→ Definition of the **Primary** and **Secondary Circulation (SC)**

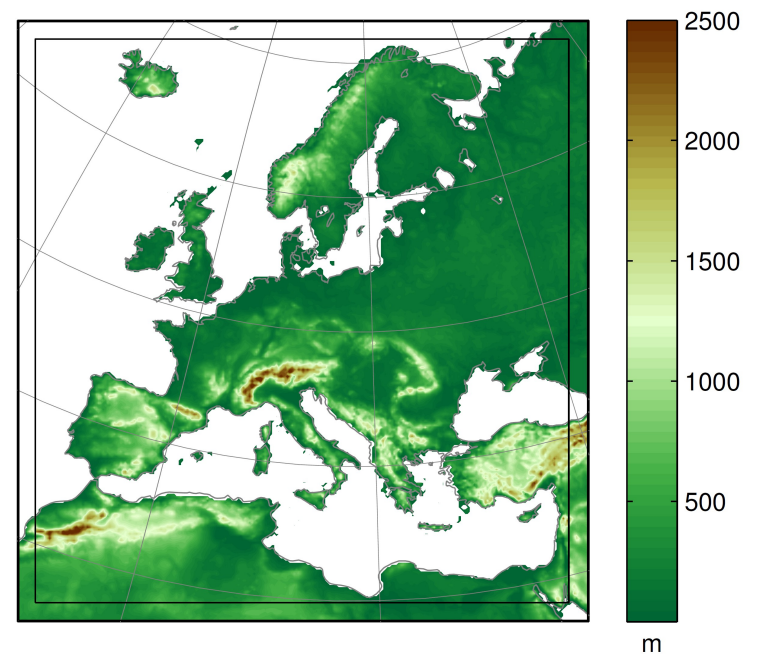

## 2) Does the SC depend on the **large-scale flow**?

### RCM

40-year CLM3 simulation  
(consortial simulations, Hollweg et al. 2008)  
Resolution:  $0.165^\circ$  (~18 km)

### GCM

ECHAM5/MPIOM  
(Roeckner et al. 2006)  
Resolution: T63 (~200 km)

## 3) Does the SC depend on the **location of the lateral boundaries**

CCLM 4.8 ensemble simulations with different model configurations

# 1.1 Splitting of the RCM wind fields

$$\vec{v}_{RCM} = \vec{v}_{GCM} + \vec{v}_{sec}$$

**RCM**
**Primary Circulation**
**Secondary Circulation**

## 40-year average at 500 hPa

- Geopot. height (RCM)
- Wind vectors (RCM)
-  Wind speed (RCM)

- Geopot. height (GCM)
- Wind vectors (GCM)
-  Wind speed (GCM)

- Geopot. height (GCM)
- Secondary circulation
-  Strength of SC

# 1.2 The Secondary Circulation

40-year average at 500 hPa

- Geopotential height (GCM) → Primary circulation
- ▶ Wind vector difference (RCM-GCM) → Secondary circulation

  $\|\vec{v}_{RCM} - \vec{v}_{GCM}\|$

  $\|\vec{v}_{RCM}\| - \|\vec{v}_{GCM}\|$

  $GPH_{RCM} - GPH_{GCM}$

Wind speed anomalies as in Miguez-Macho et al. (2004)

GPH anomaly as in Jaeger et al. (2008)

# 2.1 Clustering approach

Does the secondary circulation depend on the large-scale flow?

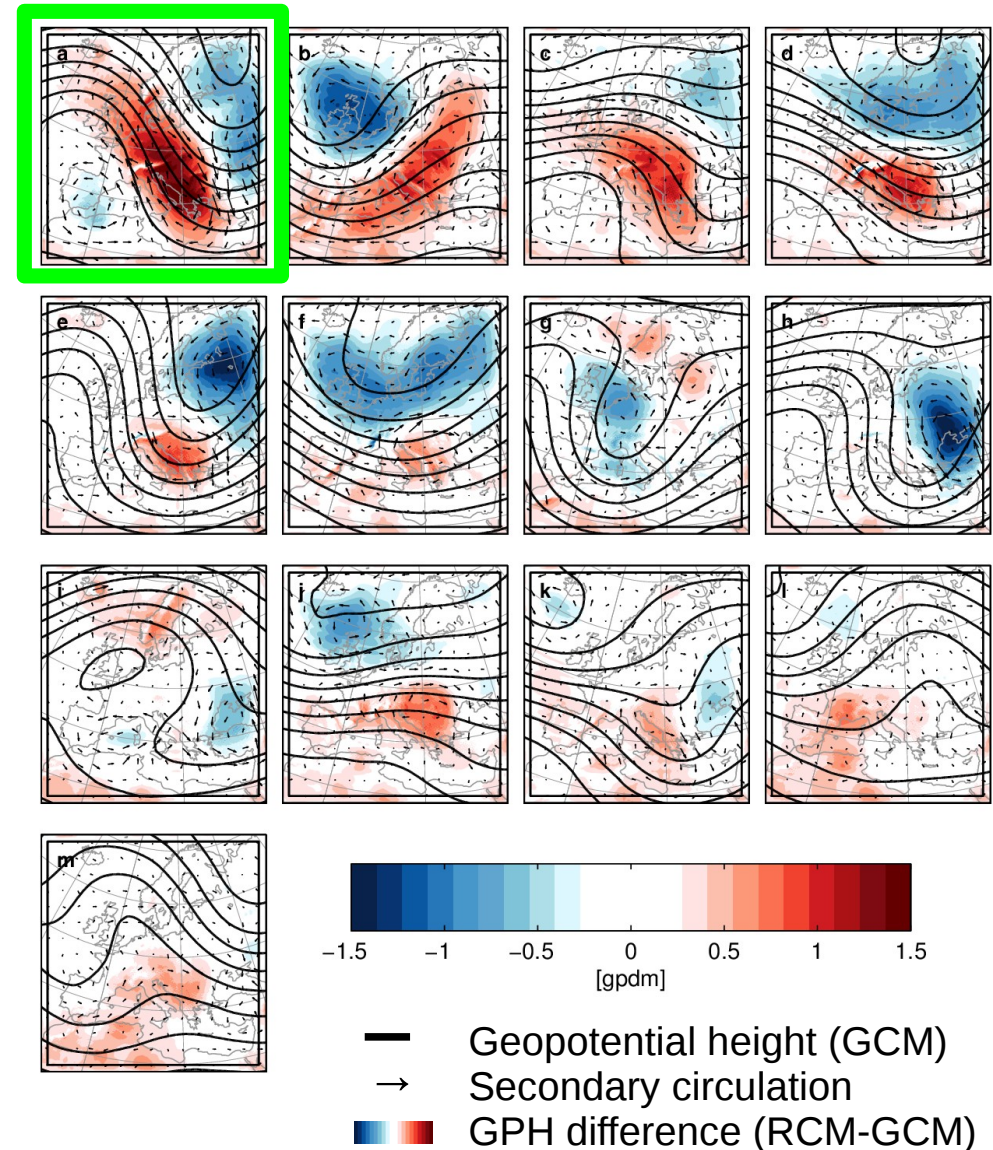

## Step 1:

- **Clustering of the large scale flow**
- Method:
  - Simulated Annealing and Diversified Randomization (*Philipp et al. 2007*)
  - Clusteranalysis based on *k*-means
- Data used for clustering:
  - Primary Circulation (GCM)
  - ECHAM5 GPH at 500 hPa

## Step 2:

- **Calculating the average SC fields for each cluster of the large-scale flow**

13 clusters, 500 hPa, for DJF

# 2.2 Clustering approach

## Cluster (a) with the strongest SC (500 hPa)

### Contours:

→ Strong north-westerly flow crossing the Alps

### Vectors and colors:

→ Tripole pattern in the SC field

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
-  GPH difference (RCM-GCM)

# 2.3 Clustering approach

## Cluster (a) with the strongest SC (500 hPa)

**Higher wind speeds** in RCM due to stronger flow around the Alps

Secondary circulation **parallel to model boundary**

**Lower wind speeds** in the RCM downstream of the Alps (increased orographic drag)

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
- Wind speed differences (RCM-GCM)

# 2.4 Driving mechanism

What causes the secondary circulation? 

## Thought experiment

- Idealized 2D model domain
- Solid boundaries
- Non-rotating system
- Acceleration in the center
- A **“balancing flow”** evolves

How does the location of the model boundaries affect the SC?

# 3.1 Impact of the model boundaries

## CCLM 4.8 simulations with different model configurations

- incremental shifts of the eastern model boundary
- incremental shifts of the southern model boundary
- ...

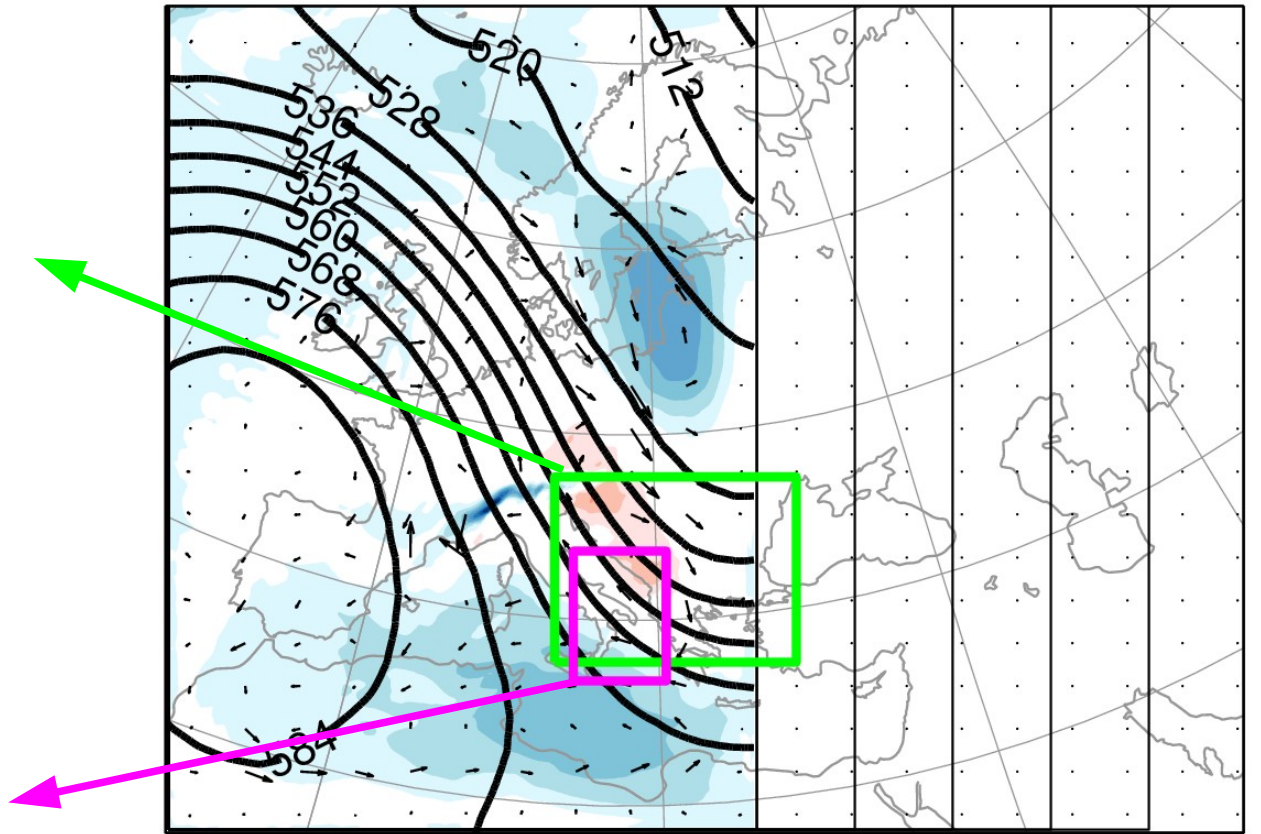

## How to select an appropriate simulation period?

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

Standard domain – 64 grid boxes

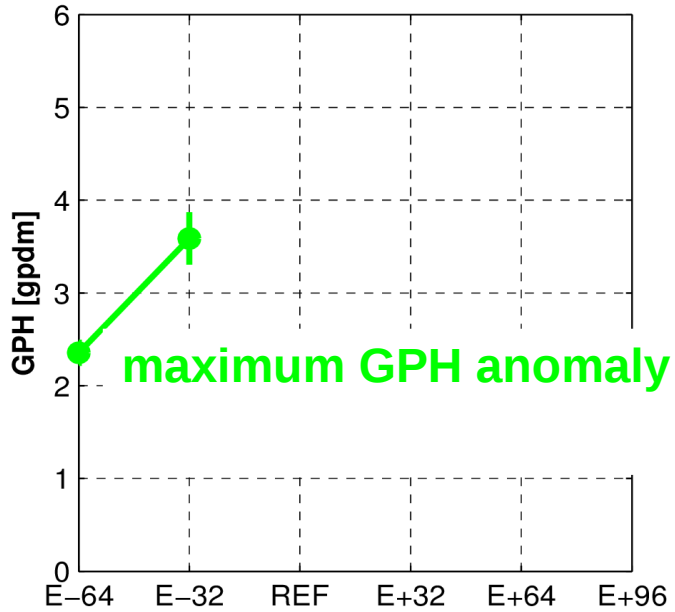

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
- GPH difference (RCM-GCM)

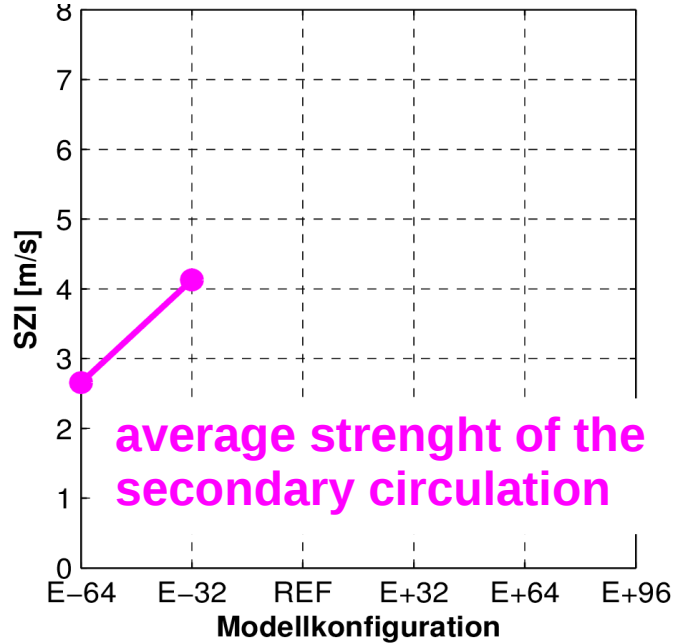

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

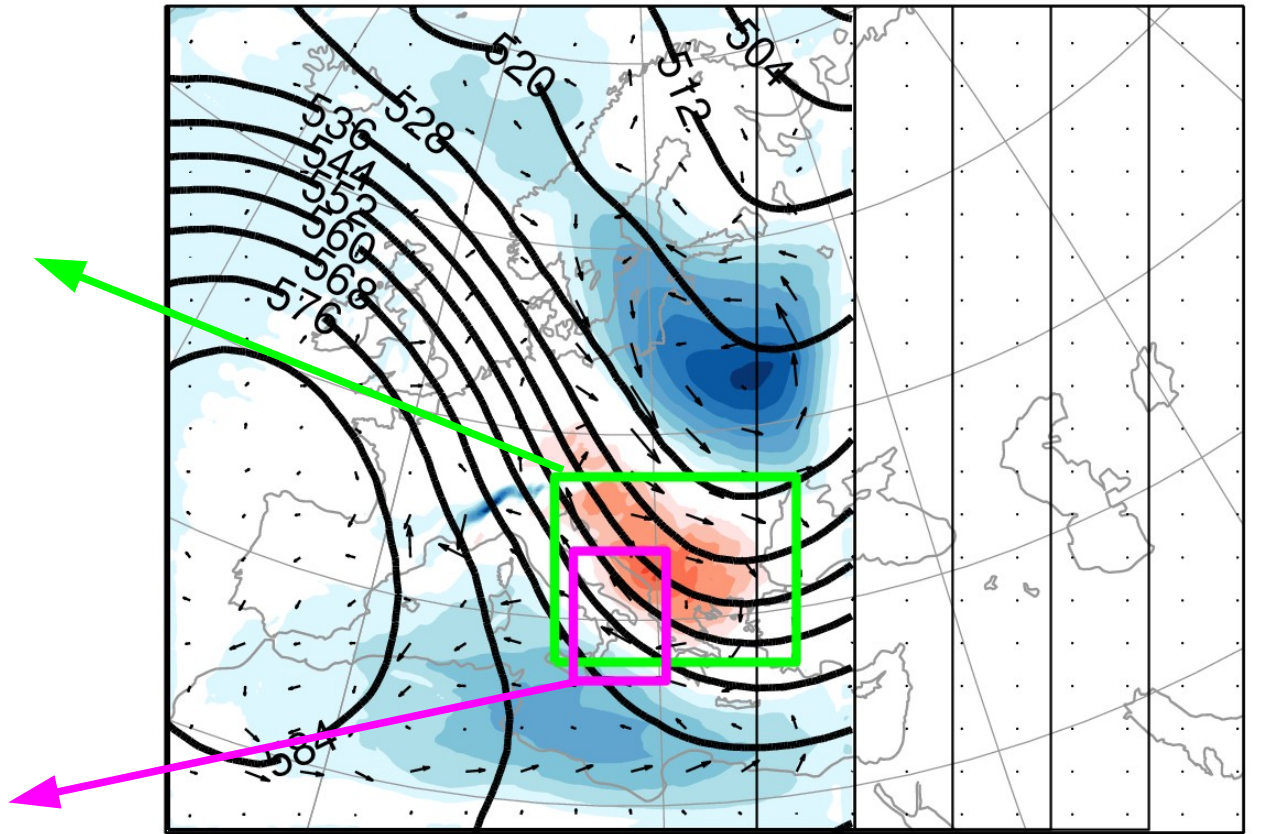

Standard domain – 32 grid boxes

maximum GPH anomaly

average strenght of the secondary circulation

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
- GPH difference (RCM-GCM)

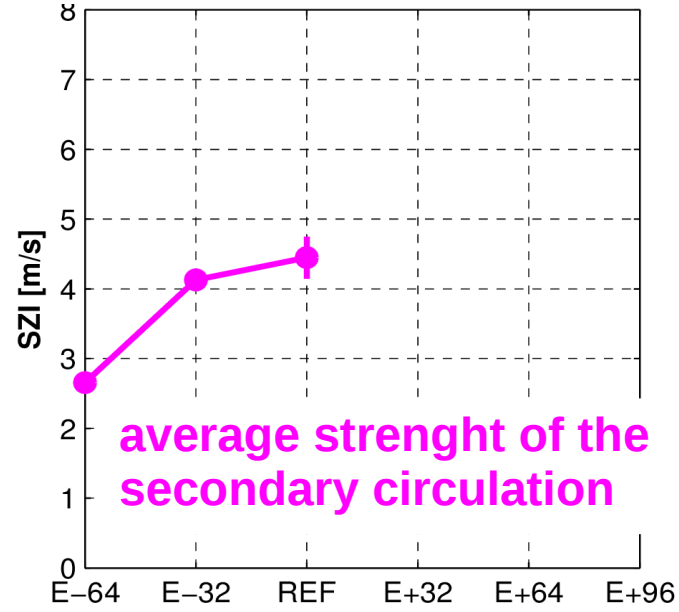

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

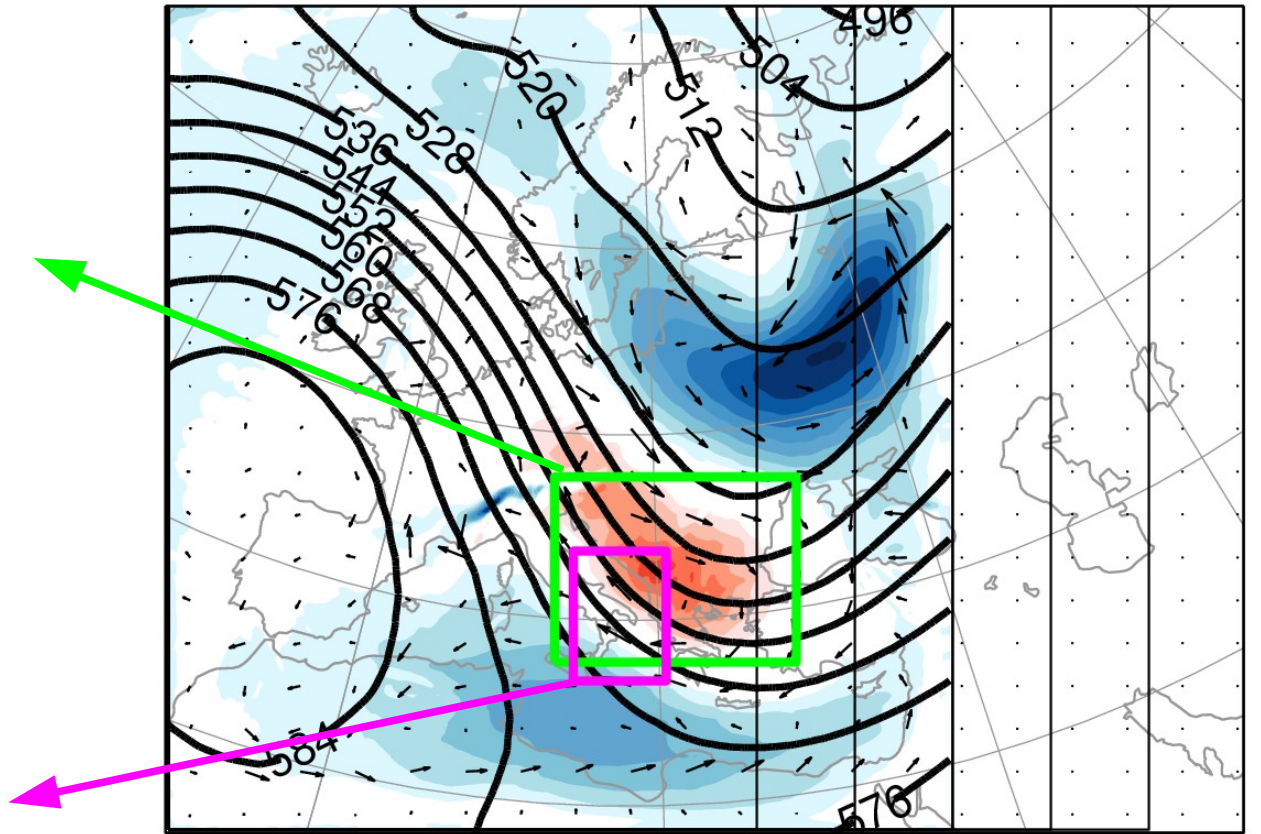

Standard domain

maximum GPH anomaly

average strenght of the secondary circulation

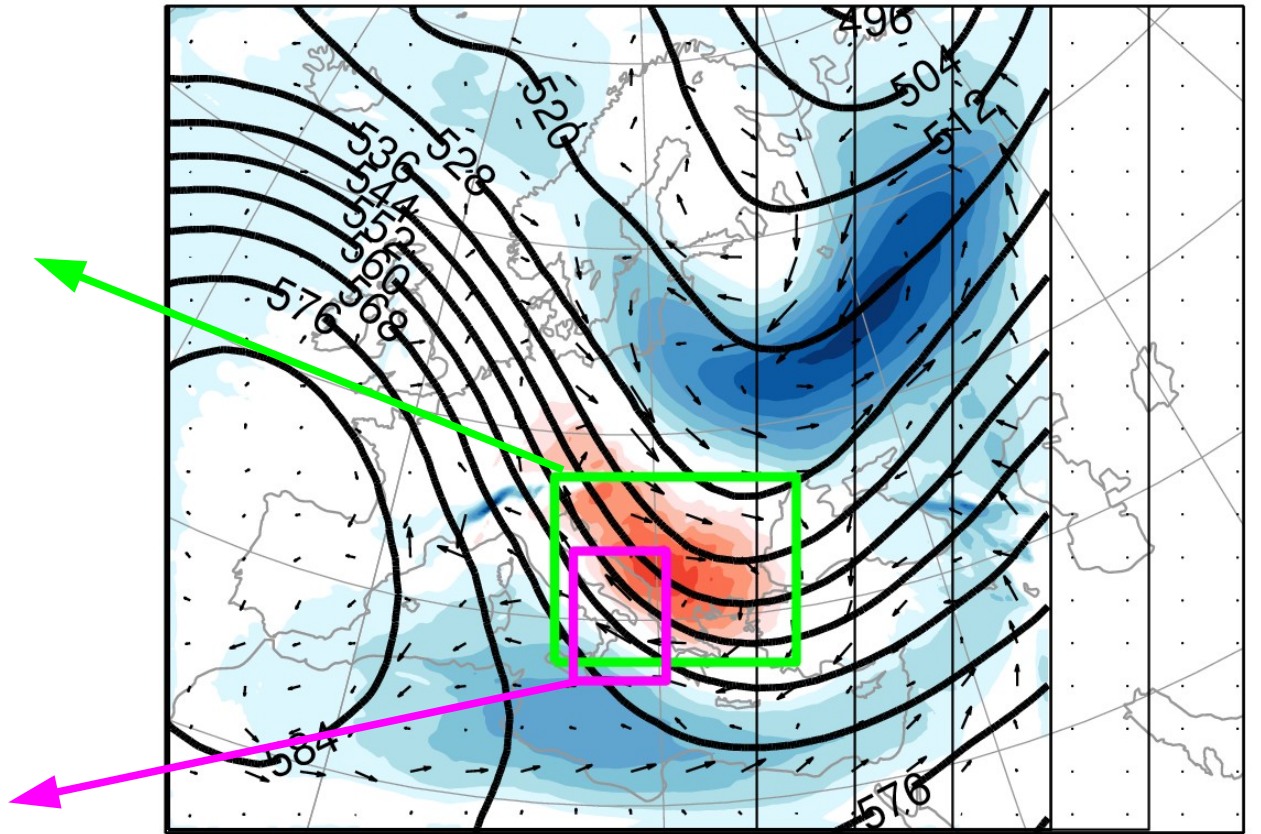

-5 0 5  
gpdm

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
- GPH difference (RCM-GCM)

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

Standard domain + 32 grid boxes

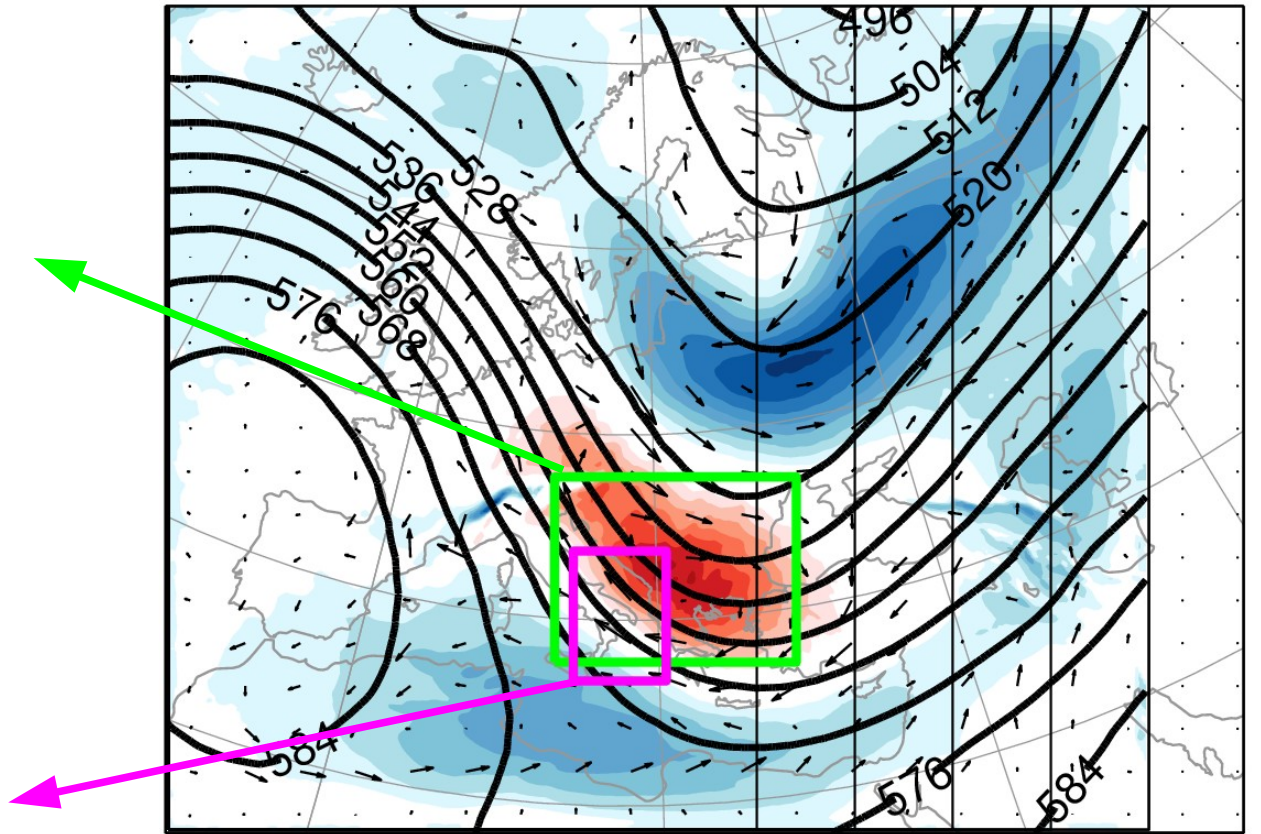

-  Geopotential height (GCM)
-  Secondary circulation (RCM-GCM)
-  GPH difference (RCM-GCM)

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

Standard domain + 64 grid boxes

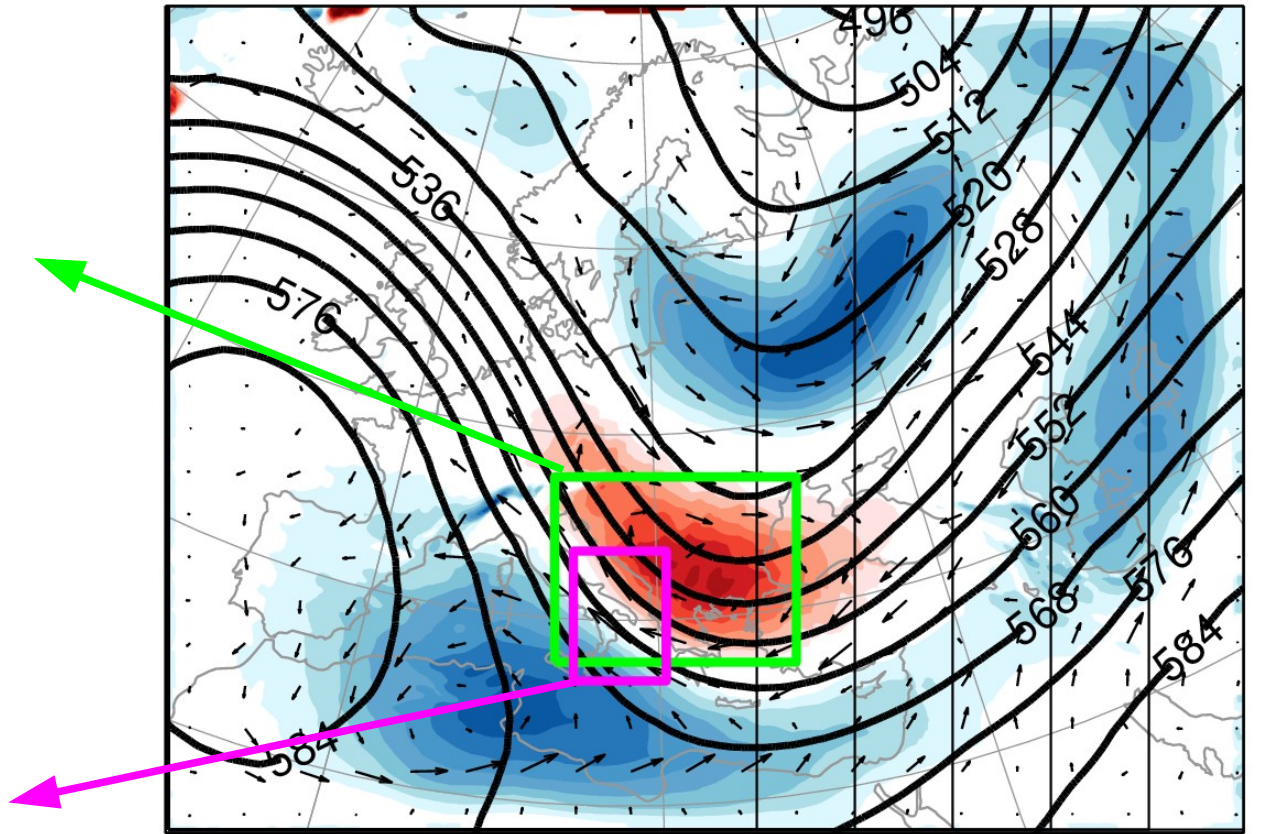

- Geopotential height (GCM)
- Secondary circulation (RCM-GCM)
- GPH difference (RCM-GCM)

# 3.2 Impact of the model boundaries

## Shifting the eastern boundary

Standard domain + 96 grid boxes

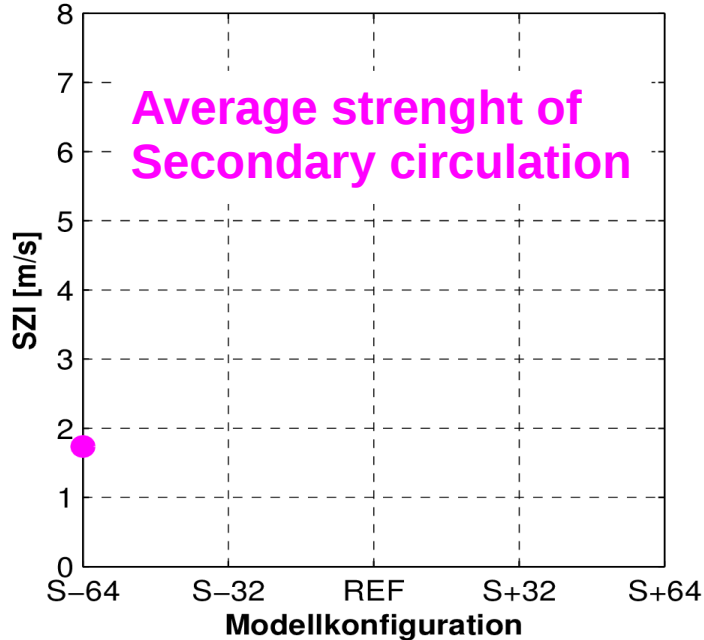

-  Geopotential height (GCM)
-  Secondary circulation (RCM-GCM)
-  GPH difference (RCM-GCM)

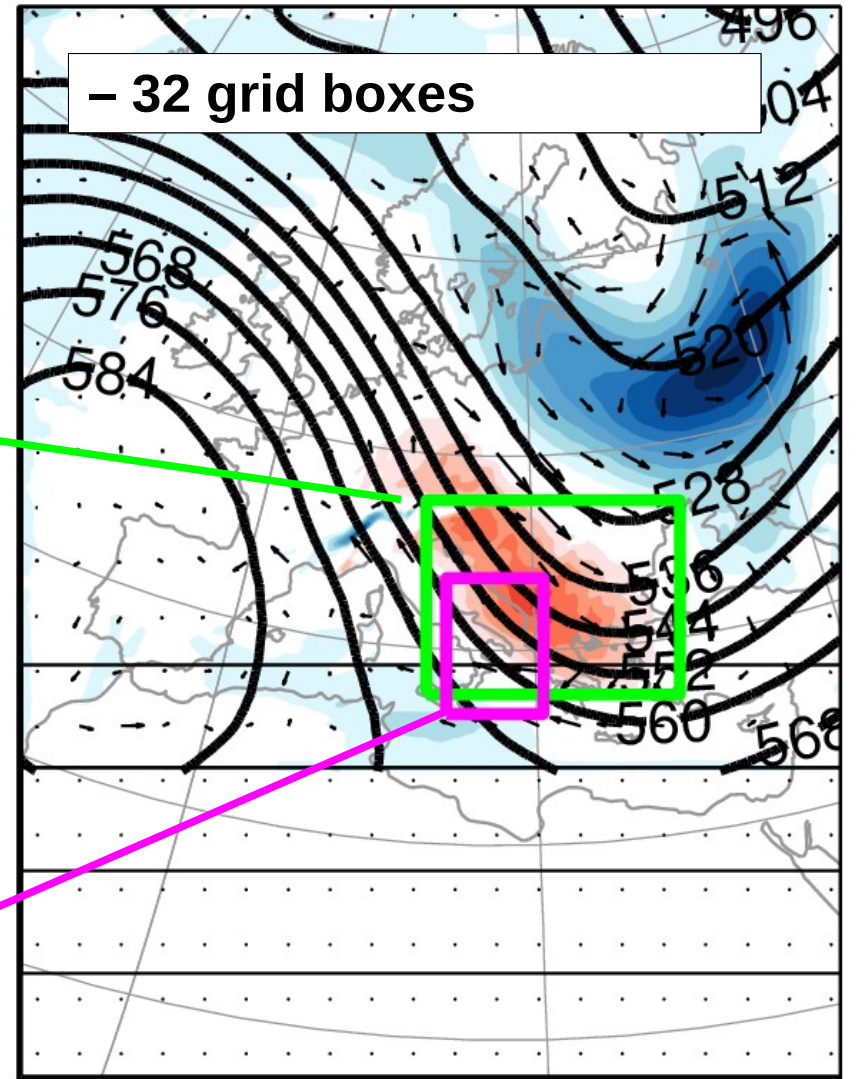

# 3.3 Impact of boundaries

## Shifting the southern boundary

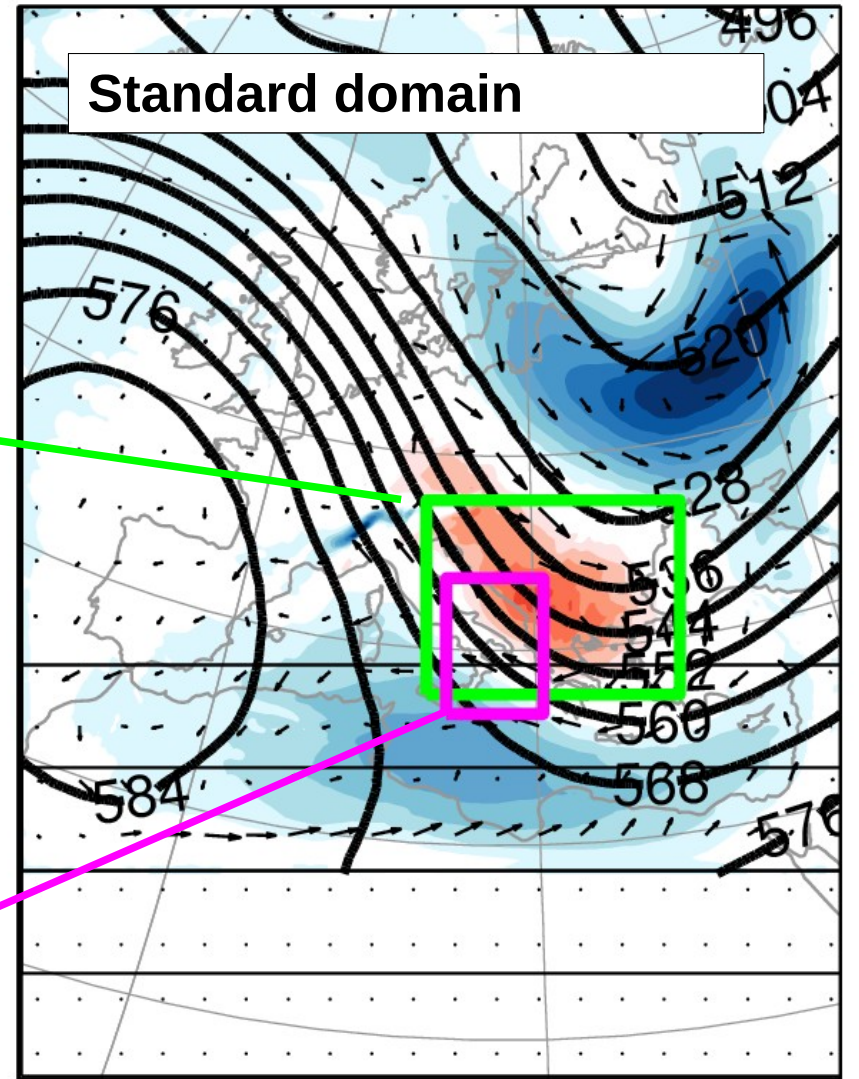

# 3.3 Impact of boundaries

## Shifting the southern boundary

# 3.3 Impact of boundaries

## Shifting the southern boundary

# 3.3 Impact of boundaries

## Shifting the southern boundary

# 3.3 Impact of boundaries

## Shifting the southern boundary

# Summary

- A **secondary circulation** exists in COSMO-CLM relative to the forcing data
- Driving mechanism of the secondary circulation:
  - **Modifications of the mass flux** in the RCM
  - e.g. due to different **orographic drag effects**
  - Mass flux modifications **cannot exit the RCM**
  - A **balancing flow** develops
- **“Added value”** and **“artefacts”** of the RCM are **directly linked** via the SC
  - added value → effects of a higher resolution
  - artefacts → interaction with the model boundary

**Is the secondary circulation relevant for regional climate modelling in general?**

# Discussion and Outlook

- **Common assumption:**
  - Boundary effects occur in areas „close to the lateral boundaries“
- **The SC demonstrates:**
  - The lateral boundaries affect the simulations **within the whole domain!**
  - Is it necessary to run **RCM ensembles** with different positions of the boundaries?
- The driving mechanisms indicate that the SC is a **general feature of all one-way nested RCMs**
- The effects of the SC have a similar order of magnitude as **climate change signals**
- It could be useful to include the SC into the **evaluation process of RCMs**
